Atomic force microscopy (AFM) uncovers cracks in the surface of a crack that touches a plate. T. Zwanzig, R. Hanson, and A. Schenkel, T. Zwanzig, A. H. Weidman, J. Feder, M. E. C. Guillen de la Cruz, H. Schreiber, R. B. Miller, and J. A. [van Meel][{}], C. Bustamante, J. H. Weron, L. Borst, J. H. R. [da Cruz][{}], and J. H. J. [van der Zant][{}], W. Minhajewa, G. Mul, and J. H. [Van der Zant][{}], K. Mala and G. Mul, S. Lepri, E. [van der Straeten][{}] and D. [van der Spoel][{}], G. R. Irwin, [{}1]: In contrast, one would have  $\sigma_{\text{cohesion}} = \sqrt{\gamma/\mu}$  in the case of a plain surface. [{}2]: It should be noted that we do not make any assumption on the size of the contact zone between the tip and the sample. [{}3]: We shall show later that the region close to the tip is narrow, of the order of the probe width. [{}4]: Note that this jump in  $\sigma_{\text{z}}$  is not obtained by integrating the free energy profile. To do so, the whole system should be divided in two regions where the free energy is respectively equal to  $S$ - $I$ S and  $S$ IS, and a jump of the slope in between. [{}5]: In the case of the crack trajectory presented in Fig. [{}fig:Example-of-tip-position{}], the tip position  $Sz$  is found as the average of 82157476af
